Microchannels are long, thin channels that are either straight or curved. They are one-dimensional (1-D) features; for example, they are typically straight in the XY plane but exhibit a sinusoidal or other curved profile in the Z direction. Microchannels may have various cross-sectional shapes and may be used in a variety of applications. The most common applications include microscale liquid handling systems, such as, liquid chromatography, microfluidics, cell sorting, and DNA analysis. However, microchannels may have a variety of other applications, including, but not limited to, microscale chemical reactors, biochemistry, DNA analysis, and pharmaceutical development. In addition, hydrophilic microchannels may be used for isolating and separating particles that are suspended in a liquid as disclosed in, for example, U.S. Pat. Nos. 5,599,587 and 5,705,075, the contents of both of which are incorporated herein by reference in their entirety. In these patents, a microchannel including a cross-sectional area that is smaller than the cross-sectional area of the particles suspended in a liquid is used to separate the particles from the suspension. The particles are transported through the microchannel by controlling the liquid entering the microchannel. Some applications for microchannels may require similar channel lengths to provide for a desired separation time. In such applications, it may be desirable to use a microchannel having a length that is larger than the length of the particles to be separated. The larger the length of the microchannel, the longer the time required for the particles to travel through the microchannel. Thus, where shorter separation times are required, it may be desirable to use microchannels having a length that is smaller than the length of the particles to be separated. However, as microchannels are scaled-up in length, the pressure drop across the microchannel typically increases. Thus, larger pressures are required to provide the desired flow rates. This leads to problems when using such microchannels. For example, the injection pressure required to induce the desired flow rate is no longer practical. Such a pressure may damage the microchannel or the molecules that are flowing through the microchannel. These problems may be solved by reducing the size of the microchannel. However, where smaller microchannels are used, flow rates that are lower than the desired flow rate may still be achieved. One such application requiring a high flow rate at a high pressure is microscale liquid handling
